Introduction

- Beginning with a city, a salesman wants to visit all the cities and end up in the starting city
- But travelling costs money
- So how to find a cheap tour?

TSP graph formulation

- Represent each city as a vertex

TSP graph formulation

- Represent each city as a vertex
- Each city is connected to all the other cities by edges (complete graph)

TSP graph formulation

- Represent each city as a vertex
- Each city is connected to all the other cities by edges (complete graph)
- Cost of traveling between cities is represented by weights of the edges.

TSP graph formulation

- Represent each city as a vertex
- Each city is connected to all the other cities by edges (complete graph)
- Cost of traveling between cities is represented by weights of the edges.
- A tour is a hamiltonian cycle of the graph. Cost of the tour is sum of the edges in the hamiltonian cycle

cost of tour = 80

TSP Optimization Version

- Find the tour with the minimum cost
- NP-hard but not NP-complete. Because there's no efficient way to verify if the solution is optimal.

cost of optimal tour = 66

TSP Decision Version

- for a certain value k , is there a tour with cost $\leq k$?
- NP-Complete.[NP-hard and a given instance can be verified in polynomial time]

For $k = 85$: cost of tour = $80 < k$

TSP Formal Definition

- Cost: c_{ij} = cost of travelling between cities i and j
- Number of cities: n
- Cyclic permutation of cities: $k(1), k(2), \dots, k(n), K(1)$ where each city j is listed as a unique node $k(j)$.
- Then, cost of the tour is
$$C(\pi) = C_{k(n)k(1)} + \sum_{i=1}^{n-1} C_{k(i)k(i+1)}$$
- Goal of the problem: Find permutation π such that $C(\pi)$ is minimum

Different types of TSP

- **Symmetric TSP (sTSP):** For this type of TSP problem, weights of edges between two vertices are symmetric [$c_{ij} = c_{ji}$ where c_{ij} denotes cost of travelling from i to j]
- **Asymmetric TSP (aTSP):** For this type of TSP problem, weights of edges between two vertices are not always symmetric [$c_{ij} \neq c_{ji}$ where c_{ij} denotes cost of travelling from i to j]

Figure: Symmetric TSP

Figure: Asymmetric TSP

Different Types of TSP

- **Multiple TSP(mTSP):** In a given set of nodes, let there are m salesmen located at a single depot node. The remaining nodes (cities) that are to be visited are intermediate nodes. Then, the mTSP consists of finding tours for all m salesmen, who all start and end at the depot, such that each intermediate node is visited exactly once and the total cost of visiting all nodes is minimized.

Figure: Multiple TSP

No constant Factor Approximation for TSP

There is no constant factor approximation for TSP, unless $P=NP$

- We will prove this Theorem using contradiction.
- Suppose, There is a ρ approximation algorithm for TSP. Let $G=(V,E)$ be an unweighted graph. $|V| = n$
- Construct G' from G by adding edges and assigning weights to them as follows:
$$c_{ij} = \begin{cases} 1 & \text{if } (i,j) \in E \\ n\rho & \text{if } (i,j) \notin E \end{cases}$$

No constant Factor Approximation for TSP

There is no constant factor approximation for TSP, unless $P=NP$

- We will prove this Theorem using contradiction.
- Now Suppose we run an approximate TSP solver on G' . If G has a hamiltonian cycle, then G' has a TSP of total cost n , otherwise, TSP will give a total cost greater than $n\rho$.
So using approximation algorithm, we solved the hamiltonian cycle problem in polynomial time. But this is not possible unless $P=NP$.
- Hence, The theorem is proved.

cost of TSP $> 3\rho$. No hamiltonian cycle

Different Types of TSP

- **Metric TSP:** The input to TSP is called metric if for each triplets of vertices, the triangle inequality holds.
That means, if $i, j, k \in V$, $c_{ik} \leq c_{ij} + c_{jk}$.
 - Approximate Algorithms exist for metric TSP.

Figure: Metric TSP

Exact Algorithms For TSP

Brute-force search

Approach: Try all permutations

Complexity: $O(n!)$

Suitable only for a small network with few cities

Held-Karp algorithm

Approach: Dynamic programming

Complexity: $O(n^2 2^n)$

Suitable for an intermediate number of cities

Concorde TSP solver

Approach: Branch-and-cut-and-price

Can solve for a network of 85,900 cities but taking over 136 CPU-years

Christofides Algorithm - Pseudocode

Algorithm Christofides algorithm

Require: A complete weighted $G = (V, E, w)$ graph with Metric Property

Ensure: Hamiltonian cycle H with approximate minimization of cost

- 1: Create a minimum spanning tree(MST) T of the given graph G .
 - 2: Let O be the set of vertices with odd degree in T .
 - 3: Find a minimum weight perfect matching M in the induced subgraph given by the vertices from O .
 - 4: Combine the edges of M with the edges of T to form a multigraph H in which each vertex has even degree.
 - 5: Form an Eulerian circuit in H .
 - 6: Make the circuit found in previous step into a Hamiltonian circuit by skipping visited vertices (shortcutting).
-

Christofides Algorithm

Figure: Original Graph

Initially $G(V, E)$ is complete.

Christofides Algorithm - MST

Figure: Minimum Spanning Tree

Use Kruskal's Algorithm
 $O(E \log V)$ Time Complexity

Christofides Algorithm - Odd Vertices

Figure: Odd Vertices in MST

Eulerian path needed.
Each vertex needs to have 2 degree exact.
We find odd degree vertices.
Which are 0, 1, 2, 5.

Christofides Algorithm - Minimum Cost Matching

Figure: Minimum Cost Matching

Create their subgraph and
find minimum cost matching.
 $O(n^3)$ time complexity.

Simulated Annealing Flow Chart

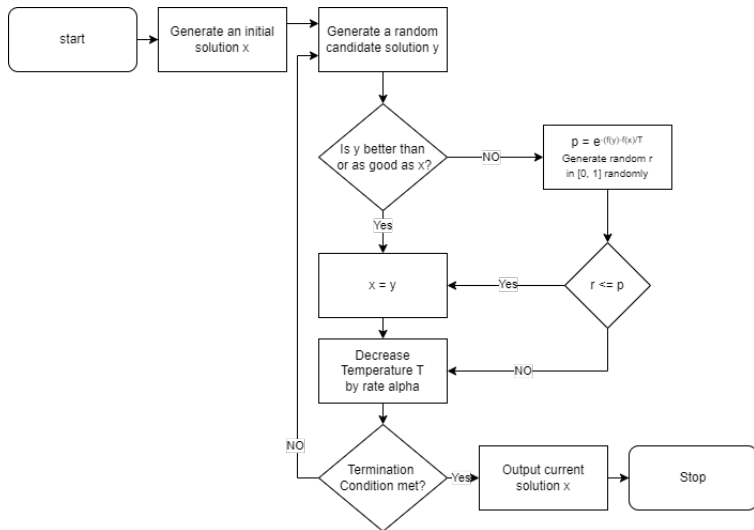

Figure: Simulated Annealing

Initial Solution

- Permutations of $\{1, \dots, n\}$
- Representation: $[1, 2, 3, 4, 5, 6, 7, 8, 1]$

Algorithm 1 Simulated Annealing Pseudo-code

```
1: nodes  $\leftarrow$  list of all nodes in the graph
2: curr_node  $\leftarrow$  randomly choose a node from nodes
3: initialize current_solution as a list containing curr_node
4: available_nodes  $\leftarrow$  set of all nodes in the graph
5: available_nodes  $\leftarrow$  available_nodes  $\setminus$  {curr_node}
6: while available_nodes  $\neq \emptyset$  do
7:   next_node  $\leftarrow$  node in available_nodes with minimum edge weight from
     curr_node
8:   available_nodes  $\leftarrow$  available_nodes  $\setminus$  {next_node}
9:   current_solution  $\leftarrow$  current_solution + {next_node}
10:  curr_node  $\leftarrow$  next_node
11: end while
```

Figure: Initial Solution

Definition of Neighbor

Figure: Current Tour

Figure: Candidate Neighbor

Fitness Function

- $f(x)$, measures the performance of the solution candidate
- in our case, the total length of the tour
- e.g.: Candidate Solution, $S = (S_1, \dots, S_i, \dots, S_n)$
$$C(S) = \sum d(S_i, S_{i+1})[1 \leq i \leq n-1] + d(s_n, s_1)$$

Controlling Temperature

- denoted by T
- $T = T - \alpha * T$; α is the cooling parameter

Termination Condition

- Maximum number of iterations
- $T \leq 0$

Revisiting Christofides

- Christofides algorithm is deterministic.
- May use Kruskal's algorithm or Prim's algorithm as a subroutine to obtain MST.

Algorithm 1 KRUSKAL-MST

Require: A connected, undirected, weighted graph $G = (V, E)$

Ensure: A minimum spanning tree T of G

```
1:  $T \leftarrow \emptyset$ 
2: for  $v \in G.V$  do
3:   MAKE-SET( $v$ )
4: end for
5:  $E \leftarrow LIST(G.E)$ 
6: Sort  $E$  in non-decreasing order by weight
7:  $i \leftarrow 0$ 
8: while  $|T| < |G.V| - 1$  do
9:    $e \leftarrow E[i]$ 
10:  if FIND-SET( $e.u$ )  $\neq$  FIND-SET( $e.v$ ) then
11:     $T \leftarrow T \cup \{e\}$ 
12:    UNION( $e.u, e.v$ )
13:  end if
14:   $i \leftarrow i + 1$ 
15: end while
16: return  $T$ 
```

Time Complexity Analysis of KRUSKAL-MST

- $|V|$ MAKE-SET operations take $O(V \log V)$
- Sorting E takes $O(E \log E) = O(E \log V)$
- $|E|$ FIND-SET and UNION operations take $O(E \log E) = O(E \log V)$
- For complete graphs, $|E| = O(V^2)$
- Thus, total time complexity is $O(E \log V) = O(V^2 \log V)$

Trying Other STs

- MST may not give optimal tour.
- May try with other STs.
- **Idea:** Randomly sample an ST.
- But, does a completely random ST perform well?

Problem with Random STs

Name	Dimension	C_Ratio	R_Ratio
fri26	26	1.054429029	3.186766275
bays29	29	1.083168317	3.20049505
swiss42	42	1.09897879	3.825608798
hk48	48	1.139429369	4.826978449
brazil58	58	1.082693444	4.869895649

Algorithm 2 RANDOMIZED-ST

Require: A connected, undirected, weighted graph $G = (V, E)$

Ensure: A spanning tree T of G and a randomization parameter k

```
1:  $T \leftarrow \emptyset$ 
2: for  $v \in G.V$  do
3:   MAKE-SET( $v$ )
4: end for
5: Sort  $E$  in non-decreasing order by weight
6: while  $|T| < |G.V| - 1$  do
7:    $j \leftarrow \text{MIN}(|E|, k)$ 
8:    $W \leftarrow [e.w \text{ for } e \in E[0, j + 1]]$ 
9:    $i \leftarrow \text{SAMPLE-INDEX}(W)$ 
10:   $e \leftarrow E[i]$ 
11:  if FIND-SET( $e.u$ )  $\neq$  FIND-SET( $e.v$ ) then
12:     $T \leftarrow T \cup \{e\}$ 
13:    UNION( $e.u, e.v$ )
14:  end if
15:  ERASE( $E, i$ )
16: end while
17: return  $T$ 
```

Algorithm 3 SAMPLE-INDEX

Require: A list of weights W

Ensure: Sample a random index $i \in [0, |W|]$

- 1: Z-Normalize the values in W
 - 2: $P \leftarrow [e^{-w} \text{ for } w \in W]$
 - 3: $s \leftarrow \text{SUM}(P)$
 - 4: Sample $j \in [0, |W| - 1]$ using the probability distribution P
 - 5: **return** j
-

Time Complexity Analysis of RANDOMIZED-ST

- Additional $|E|$ calls to SAMPLE-INDEX take $O(kE) = O(kV^2)$
- $|E|$ ERASE operations take $O(kE) = O(kV^2)$
- Thus, total time complexity is $O(V^2 \log V + kV^2)$

- Use k -RANDOMIZED-ST instead of KRUSKAL-MST
